34  start_time = time.time()
35  c.execute(new_query)
36  result_after = c.fetchall()
37  new_time = time.time() - start_time
38  print("Time(After):", new_time)
39
40  print("Optimized or not (True / False)---->", new_time < before)
41
42  conn.close()
```

Output:

```
C:\PES\26\Projects\Database\Apartment>python Query_optimization.py
Time(Before): 0.0948908329010098
Time(After): 0.09401369094848633
Optimized or not (True / False)----> True
```

Topic: Apartment Management System

e) Query Analysis and Optimization:

PES1UG21CS608

lets have join query on 3 tables

- 1> Apartments
- 2> Tenants
- 3> Maintenance Request

```
SELECT t.name, a.apartment_no, m.issue-
description FROM Tenants t
JOIN Apartments a ON t.apartment-no =
a.apartment-no
JOIN MaintenanceRequest m ON m.apartment
m.apartment-no = a.apartment_no
WHERE m.status = "Pending";
```

Parse

Parse tree:

```
graph TD
    SELECT --> FROM
    SELECT --> JOIN1[JOIN]
    SELECT --> WHERE["(WHERE)"]
    FROM --> Tenants
    FROM --> Apartment
    Tenants --> t_name["t.name"]
    Apartment --> a_apartment_no["a.apartment-no"]
    JOIN1 --> JOIN2[JOIN]
    JOIN1 --> MaintenanceRequest
    MaintenanceRequest --> m_issue_description["m.issue-description"]
    JOIN2 --> m_apartment_no["m.apartment-no"]
```

Relational Algebra:-

$$\pi(t.name, a.apartment-no, m.issue-description)$$
$$(\sigma(m.status = 'Pending' \bowtie (Tenants \bowtie Apartments \bowtie Maintenance Requests)))$$

Query Tree:

```
graph TD
    SELECT --> pi
    SELECT --> sigma
    SELECT --> join1[join]
    pi --> t_name["t.name"]
    sigma --> join2[join]
    sigma --> join3[join]
    join2 --> Tenants
    join2 --> Apartment
    Apartment --> a_apartment_no["a.apartment-no"]
    join3 --> MaintenanceRequest
    join3 --> join4[join]
    MaintenanceRequest --> m_issue_description["m.issue-description"]
    join4 --> m_apartment_no["m.apartment-no"]
```

Part 2: Query Optimization:

PES1UG21CS608
Sourabha Gokavi

Optimized Query Tree

Steps

- 1> Reordering the join to optimize it.
- 2> Using correct join operation (like left, right --)
- 3> Using the index for performance optimization
- 4> we will push the where clause as down as possible to reduce the size of the intermediate results.

Relational Schema:
